

# Structural Controls on Gold Mineralisation in the Kalgoorlie Terrane, Western Australia

Project integrates geological, structural and mineral occurrence datasets in QGIS to evaluate gold distribution in relation to fault systems and lithology.

## Main Map Output:

## Interpretation

Gold mineralisation shows strong spatial association with regional fault systems, indicating structural control of fluid pathways. Lithological domains such as mafic and ultramafic units provide favourable host environments.

## Conclusion

The study confirms that gold distribution in the Kalgoorlie region is primarily structurally controlled with secondary lithological influence.

## Workflow

DEM → AOI → Fault Buffer → Spatial Selection → Geology Classification → Final Map Output
